Abstrack

*Long bean (*Vigna sinensis L.*) is a type of legume vegetable. Long beans have a high commercial value and have a very big role in meeting the nutritional food needs of the community, especially for vegetable protein needs. The increase in the production of legumes still needs to be increased, because this commodity is widely consumed by all levels of society. From several phenomena, the problem is how big the profit of long bean farming is, what factors affect the production of long bean farming, and whether farmers are efficient in using production costs in their long bean farming activities. With the progress of farming in the community in managing agriculture or plantations well, it will obtain high production results which are always expected by farmers in producing agricultural production to get maximum yields. Farming analysis is needed to further increase productivity and income. Farming analysis can help farmers to calculate their farming business from the start, reduce the risk of business failure and make it easier to get capital assistance so that their farming can run effectively and efficiently. The aim of this farming business is to obtain the highest possible income for the farmer's family. The amount of this income can be used to assess the success of farmers in managing it. The main benefit of this income is for the continuation of his farming business.*
