**ABSTRAK**

*Information systems are very helpful in processing data. To avoid errors in data processing, it is necessary to measure the functionality of the software, by measuring the functionality of the software to find out how good the quality of the information system is. Developers can find out the success rate of the system being built and the user knows the information system is suitable for use or not. However, many still don't know how to calculate software functionality. So in this study will use the function point method to measure the functionality of the information system in Koperasi Madani. The function point method is a method that can measure software functionality by determining the CFP and RCAF values. The research method that will be used is quantitative research methods, because in this study a lot of data is processed in the form of numbers. The results of the study are numbers that indicate the level of software functionality based on the CFP and RCAF values. In this study, the value of the functionality of the Koperasi Madani system is 0.73 and it can be categorized as a good system.*
